

How To Start

Follow these steps to get the **NextGen Park Simulator** running and connect your system to it. For more technical information, visit the **Documentation** page, where you can find detailed guides for **Simulator Components**, **REST API endpoints**, **Webhooks**, **Events**, **Authentication**, **Settings**, and **Penalties**.

Registration:

please register your team here : <https://forms.gle/vQyYVJtuRKuy8acL8>

Download the Simulator

Download the latest version of the Park Simulator for your platform from the **Download Page**.

 [Downloads](#)

Configure the Settings

Before starting the simulator, open the downloaded folder and go to :

`Settings/settings.json`

Configure it according to your environment. This includes your **webhook listener URL**, **server address**, **username**, **password**, and other simulator options.

For all available settings and their descriptions, see the page :

 [Settings](#)

Run the Simulator

Start the Simulator application. You will see the **live car park simulation**, while the console displays useful information such as the **REST API URL**, **server status**, **events**, and **logs**.

For details about gates, parking spots, sensors, fans, and other elements, see

 [Parking Simulator Components](#)

 [Parking Simulator API Documentation](#)

Authenticate and Get Your Token

Before calling protected API endpoints, use the **Login API** with the username and password configured in your settings.

After successful authentication, you will receive a **token/API key** to use with subsequent requests as bearer request. (Bearer Token)

Call the REST API

You can now interact with the simulator through its REST API. For example, you can **list cars, inspect parking elements, check their status, control gates**, and perform other supported operations.

Test Your Webhook Listener

The simulator sends events to your configured webhook listener, such as **car arrivals, payments, penalties, element failures, and other simulator events**.

You can trigger test events and verify that your application receives and processes them correctly.

See **Webhooks Documentation** for payload formats, signatures, event types, and examples.

Below is description image about the system components
